An object with an electric dipole moment is subject to a torque $\vec{\tau}$, when placed in an external electric field. The torque tends to align the dipole with the field. A dipole aligned parallel to an electric field has lower potential energy than a dipole making some angle with it. For a spatially uniform electric field E , the torque is given by: $\vec{\tau} = \vec{p} \times \vec{E}$, where p is the dipole moment, and the symbol ...

In the conceptual model of fundamental interactions, matter consists of fermions, which carry properties called charges and spin $\pm \frac{1}{2}$ (intrinsic angular momentum $\pm \frac{\hbar}{2}$, where \hbar is the reduced Planck constant). They attract or repel each other by exchanging bosons.. The interaction of any pair of fermions in perturbation theory can then be modelled thus:

Amazing news: Researchers in Switzerland have separated an Electron into two smaller quasi-particles â€” a â€œSpinonâ€• and an â€œOrbitonâ€• meaning they have physically separated the spin and the orbit properties of an Electron. Until now, standard physics generally accepted that an Electron was a fundamental particle â€” that it was not made of smaller components.
